

Supplemental Figure S1. The Kaplan-Meier curves of patients with non-advanced angiosarcoma. Patients with FOXM1-high angiosarcoma had significantly shorter disease-specific survival (**A**) and event-free survival (**B**) than those without high expression ($P = 0.049$ and $P = 0.014$, respectively).

Supplemental Figure S2. A: Transfection of siRNA for FOXM1 was confirmed by qRT-PCR and western blotting analyses (Mann-Whitney U-test; $***P < 0.001$). **B:** FOXM1 inhibition by thiostrepton. Both qRT-PCR and the western blot showed that FOXM1 expression levels were reduced (one-way ANOVA followed by Dunn's multiple comparison post-hoc test; $**P < 0.01$). Error bars: SD.
